## Summary

nimCSO is a high-performance, low-level tool for finding sets of components (dimensions) in compositional spaces which optimize the data availability for applications such as machine learning, which is a combinatorically hard problem for complex compositions existing in highly dimensional spaces due to the interdependency of components being present. Such spaces are often encountered in materials science, where datasets on Compositionally Complex Materials (CCMs) often span 20-40 chemical elements, while each data point contains several of them.

This tool employs a set of methods, ranging from (1) brute-force search through (2) genetic algorithms to (3) a newly designed search method. They use custom data structures and procedures written in Nim language, which are compile-time optimized for the specific problem statement and dataset pair, which allows nimCSO to run faster and use 1-2 orders of magnitude less memory than general-purpose data structures. All configuration is done with a simple human-readable config file, allowing easy modification of the search method and its parameters.

## Statement of Need

The Compositionally Complex Materials (CCMs), and their metal-focused subset of High Entropy Alloys (HEAs), belong to a rapidly emerging class of materials, first proposed by (Cantor et al., 2004) and (Yeh et al., 2004). Contrary to more traditional materials, they contain a large number of chemical elements, typically 4-9 in similar proportions, in hope to thermodynamically stabilize the material by increasing its configurational entropy, by up to  $\Delta S_{conf} = -R \sum_i x_i \ln x_i$  for ideally random mixing of  $N$  elements with fractions  $x_i$ .
